Background and objective

How biochar amendment affects plant photosynthesis and growth remains unclear, especially on a global scale. 1) obtaining a central tendency of plant photosynthesis and growth in response to biochar amendment and 2) investigating the key driving factors that affect the response of plant photosynthesis and growth following biochar amendment. Here we report only results related to crop yield.

Search strategy and selection criteria

Research literatures were searched in Web of Science, Google Scholar and China National Knowledge Infrastructure (1900–2019) with the keywords “biochar OR char OR charcoal AND photosynthesis OR photosynthetic activity OR photosynthetic rate”. 1) observations had one pair of data at lowest (comparing a control and biochar-amended treatment) and measured photosynthesis in plants; 2) the plots for all treatments had the same environmental conditions and dominant vegetation composition as the control at the beginning of the experiments; 3) the methods for biochar amendment were explicitly described, including biochar application rate and experimental duration; and 4) the mean and its standard deviation or error of variables in each treatment could be extracted from contexts or supplemental materials directly.

Data and analysis

The mean effect size was quantified by the weighted response ratio (RR++) using the random effects model. The 95% bootstrap confidence intervals (CIs) were calculated by using a bootstrapping (999 iterations) method. To examine the heterogeneity among subgrouping categories, the between-group heterogeneity (Qb) was calculated by using the MetaWin 2.1 software. We also used a random effect model to identify these biochar, soil physicochemical characteristics, and other explanatory factors which influence the response of photosynthesis to biochar amendment. Meta-regression was performed to explore the relationships between RR (photosynthesis and biomass) and continuous variables. The effects of plant type (C₃ and C₄) on physiological variables–photosynthesis and photosynthesis–biomass relationships were examined using analysis of covariance (ANCOVA).

Number of papers	Population	Intervention	Comparator	Outcome	Quality score
74	Not specified	Soil amendment with biochar	No amendment	Metric: 1) Total biomass (TB); 2) shoot biomass (SB); 3) Crop yield (CY); 4) plant height (PH); 5) and leaf area (LA); Effect size: Logarithm of ratio of the considered metrics in the intervention to the considered metrics in the control	0.8125

Results

- Total biomass (TB), shoot biomass (SB), RB, CY, plant height (PH), and leaf area (LA) were also increased by 25.4%, 22.1%, 34.4%, 17.7%, 12.9%, and 11.1%, respectively after biochar amendment.
- Root biomass was increased by 34.4% after biochar amendment.

Factors influencing effect sizes

- Crop type : Biochar amendment significantly increased TB, SB, RB, and CY by 39.2%, 36.4%, 48.1%, and 21%, respectively in the C₃ plants, which were significantly higher than those of the C₄ plants.
- Soil texture : Biochar amendment significantly increased plant biomass in soils with medium and fine texture, but no changes were observed in soils with coarse texture.

Conclusion

Plant total biomass, shoot biomass, and root biomass increased by 25.4%, 22.1%, and 34.4%, respectively.
